Chapter 6: Aerospace and Defense

1. Executive Summary

The Aerospace and Defense segment of the semiconductor industry has unique needs in terms of technology, security, supply chain, and lifecycle. Heterogeneous integration is a critical technology that intersects all of these challenges, so a Heterogeneous Integration Roadmap (HIR) that specifically targets the unique requirements of Aerospace and Defense is needed. This Roadmap identifies challenges in 5-, 10-, and 15-year horizons and provides guidance on how to meet those challenges. This is, of course, a perpetual work-in-progress and will be updated as capabilities move forward and new requirements arise.

Initial Scope

This initial version of the A&D chapter is focused largely on challenges and requirements for the U.S. Aerospace and Defense Industry. The intent of the Heterogeneous Integration Roadmap is to create a document that provides guidance that is useful to the semiconductor community around the world, so the US-centric viewpoint should be seen as just the starting point for this work. There are certainly many technical challenges that are pervasive throughout the international A&D industry, such as reliability, bandwidth, thermal management, radiation hardening, long product development cycles and lifetime, and supply chain security, so much of the content can be generalized beyond the US Aerospace and Defense Industry. Future revisions of this chapter will reflect that broader scope.

2021 Update

The global chip shortages that have affected many industries including aerospace and defense have led governments to respond by making investments in infrastructure for microelectronics. In 2017, the Obama White House issued the President’s Council of Advisors on Science and Technology (PCAST) report stating the importance of semiconductor innovation for economic competitiveness and national security.¹

The Semiconductor Industry Association (SIA) and the Boston Consulting Group (BCG) issued a joint report stating that the U.S. government has a strategic opportunity to reverse the decades-long trajectory of declining chip manufacturing in America, strengthen national security and make our supply chains more resilient, and make our country one of the most attractive places in the world to produce semiconductors, which are the brains of modern technology.² Figure 1-1 summarizes the key highlights of the SIA/BCG report. The conclusions are that the federal government must invest boldly in chip manufacturing incentives to make the U.S. more cost-competitive with other countries for the U.S. economy and national security:

- **Finding 1:** A strong domestic semiconductor manufacturing presence is critical to America’s economic competitiveness, national security, and supply chain resilience.
- **Finding 2:** The share of global semiconductor manufacturing located in the U.S. has plummeted in recent decades, mostly because competing governments offer large incentives and the U.S. does not.
- **Finding 3:** Robust federal incentives for semiconductor manufacturing are needed to strengthen national security, attract substantial chip manufacturing to the U.S., and create tens of thousands of American jobs.

Megan Gates of Asia Online states:³

“The United States has taken some of these steps, such as reforming the U.S. Department of Treasury’s Committee on Foreign Investment in the United States’ (CFIUS) review model to limit foreign investment in technologies – like semiconductors – in the United States; the Defense Advanced Research Projects Agency’s (DARPA’s) $1.5 billion, five-year investment into the U.S. semiconductor industry; enacting the CHIPS for America Act; and the U.S. Senate’s passage of the U.S. Innovation and Competition Act, which provides $52 billion to implement the CHIPS Act.”

¹ REPORT TO THE PRESIDENT Ensuring Long-Term U.S. Leadership in Semiconductors, January 2017, Online at: https://obamawhitehouse.archives.gov/sites/default/files/microsites/ostp/pcast_ensuring_long-term_us_leadership_in_semiconductors.pdf

Many of these needs and challenges that this chapter has identified in the previous HIR editions for microelectronics and advanced packaging for national security are now finally being addressed. The impacts of these programs will not be felt for years to come, since it takes time to build new factories and to hire the skilled workers to run them. The attention from DARPA has shifted from R&D activities to capability building. This 2021 Aerospace and Defense chapter includes: 1) updates on government-funded microelectronics programs like RAMP, RAMP-C and SHIP; 2) recent industry announcements on investments in on-shore manufacturing to strengthen the supply chain; and 3) an updated version of the A&D roadmap table.

2. HIR Aerospace and Defense Working Group

2.1 Mission Statement for the Aerospace and Defense TWG

The mission of the HIR Technology Working Group (TWG) for Aerospace and Defense (A-D) is to identify challenges, provide guidance, and recommend solutions to the A-D profession (industry, academia, and government) with sufficient lead time that they do not become roadblocks that prevent the continued implementation of leading-edge electronics in aerospace and defense systems.

There is the need to address heterogeneous integration technologies for new capabilities for embedded high-speed computing, cyber, sensors, C4ISR, signal processing, radar, and RF/analog, all while addressing unique constraints and requirements such as security, reliability, small production volumes, and long lifecycle timelines. That progress is essential to the future growth of the industry and the realization of the promise of continued impact on aerospace, defense and security applications.

The approach is to identify the requirements for heterogeneous integration in the A-D electronics industry with 5-, 10- and 15-year horizons, determine the difficult challenges that must be overcome to meet these requirements and, where possible, identify potential solutions and synergies between the greater commercial sectors and the smaller A-D community.

2.2 The TWG for Developing the Heterogeneous Integration Roadmap for Aerospace and Defense

The Goal for the A-D Technology Working Group (TWG) is to develop a roadmap for heterogeneously integrated components for applications in the Aerospace and Defense sector which want to leverage heterogeneous integration technologies that are available in the commercial marketplace but with special needs and challenges.

Specific goals:
- Identify the A-D-specific challenges in the next 5-, 10- and 15-year horizons
- Identify promising solutions and technologies
- Identify any unaddressed challenges and the types of solutions/technologies needed

Figure 1-1. Infographic on the State of Semiconductor Manufacturing in the U.S. (SIA)
• Document all of these as a chapter in the overall HIR document
• Continue monitoring and analyzing the A-D semiconductor and packaging space to update the roadmap in the next version of the HIR

Much of the content of this initial version of the A-D chapter is on 2.5D integration technologies, largely because of the industry's progress and focus on 2.5D, as well as significant overlap with commercial 2.5D approaches. We anticipate that future revisions will add significant content on 3D integration and other approaches such as wafer-level fan-out as A-D requirements evolve and multiple solutions are needed.

3. Introduction and Motivation

For over 70 years, the US government (USG) has worked closely with the semiconductor industry to help foster the semiconductor ecosystem to be what it is today. In the early years before the mass proliferation of consumer electronic devices, the government was the primary driver of technology. Many of the available technologies originated in USG-funded research and development (R&D) programs. Prominent examples include printed circuit boards, GaAs devices, micro-electro-mechanical systems (MEMS), the fundamental technology of the internet, global positioning systems (GPS), and much of the technology needed for 5G. Funding for development of transistors and then ICs in the ‘50’s and ‘60’s, with the USG as the primary initial customer, resulted in the moon landing over 50 years ago. In recent years, commercial applications such as personal computers, mobile devices, and now the Internet of Things (IoT) have created an enormous production demand and business opportunity that is the primary focus of the semiconductor industry. As a result, microelectronics for A-D needs is a small fraction of the total semiconductor market and therefore has a diminished impact on industry roadmaps. Additionally, R&D investments by the Department of Defense have stagnated recently, as shown in Figure 3-1, although there are signs in 2021 that this is changing for semiconductors.

From an Aerospace-Defense (A-D) perspective, having continued access to advanced semiconductor technology is important not only for national defense but for the country’s economic vitality. In the recent US President’s Council of Advisors on Science and Technology (PCAST) report, it states:

“The global semiconductor market has never been a completely free market: it is founded on science that historically has been driven, in substantial part, by government and academia; segments of it are restricted in various ways as a result of national-security and defense imperatives; and it is frequently the focus of national industrial policies. Market forces play a central and critical role. But any presumption by U.S. policymakers that existing market forces alone will yield optimal outcomes – particularly when faced with substantial industrial policies from other countries – is unwarranted.”

The USG’s National Defense Strategy was published in 2018. Key take-aways that highlight challenges include:

• “Platform electronics and software must be designed for routine replacement instead of static configurations that last more than a decade” and must also “deliver performance at the speed of relevance.”
• “New commercial technology will change society and, ultimately, the character of war. The fact that many technological developments will come from the commercial sector means that state competitors and non-state actors will also have access to them, a fact that risks eroding the conventional overmatch to which our Nation has grown accustomed.”

Modern warfare is increasingly dependent on microelectronics capabilities that sense the environment, convert the signals into data streams, process the information, and generate a response. In this sense, A-D systems are quite similar to commercial systems that perform communications and computations, while taking advantage of the advancement of semiconductor density, functionality, and cost reduction due to Moore’s Law. There is the ever-increased demand for more data throughput through wired and wireless systems. Cellular systems have migrated from 3G to 4G and now 5G architectures, which improves bandwidth ~10X with each generation. DoD systems for communications, radar, and sensing generally require wider bandwidths, higher dynamic range, and higher transmit power, as well as specialized frequency bands and security requirements that the commercial side does not require.

Figure 3-2 highlights the direction of the next generation of warfare and enabling systems for a system-of-systems

---

5 https://obamawhitehouse.archives.gov/sites/default/files/microsites/ostp/PCAST/pcast_ensuring_long-term_us_leadership_in_semiconductors.pdf
framework. The challenges in the A-D space overlap those in the commercial world but extend beyond those as noted above.

Figure 3-1. US DoD funding historical perspective.7

Figure 3-2. Notional future warfighting systems architecture.

3.2 NDIA Trusted Microelectronics Study

In 2017, the National Defense Industrial Association (NDIA) conducted a study of Trusted Microelectronics which resulted in the following recommendations for action.8

Create a U.S. National Semiconductor Strategy

“The absence of a comprehensive national semiconductor strategy was viewed ... as a major impediment to assuring access to critical national security technologies and to U.S. technological competitiveness.”

Adapt DoD Acquisition Practices to Align with the Commercial Market

Noting the “differences between DoD’s acquisition practices and commercial sales priorities,” the report “recommends defense programs be provided new methods to purchase technology on commercial terms after the commercial products have been evaluated for trustworthiness.”

Increase DoD Market Influence

Since “the DoD’s share of the semiconductor market has dramatically declined to less than a 1% share of today’s semiconductors consumption and the Department’s ability to gain access to needed microelectronics capabilities has correspondingly diminished, ... increase market influence by exchanging research investment for access to commercial products; and, aggregating demand across DoD programs, other USG offices, and non-USG industries that have similar component and system integrity concerns.”

Adopt New Trust and Assurance Models

“Defining the boundaries for assurance spectrums or ‘tiers of trust’ levels, and would cover component categories beyond ASICs.”

Launch R&D to Achieve Trust/Security in Un-trusted Fabs

“Launching near-term research and development to address the security concerns of existing commercial technology capabilities, including Trusted 3D/2.5D integration, to leverage these capabilities for defense systems.”

Two of the four NDIA Trusted Microelectronics Joint Working Groups (TM JWGs) studied the microelectronics landscape and made recommendations that relate to heterogenous integration. NDIA TM JWG Team 1 addressed the Future Needs & System Impact of Microelectronics Technologies, asking the following questions:9

- “What are the future microelectronics capabilities needed by defense contractors to maintain our technical advantage?”
- “Are there new hardware paradigms on the horizon that could be disruptive?”
- SYSTEMS: System Needs and System Capabilities: What are the future requirements for DoD Systems?
- ENABLING COMPONENTS: What are the emerging technologies enabling these capabilities at the component level?
- ADOPTION: What are the risks regarding secure component availability (5-10 years) that enables system capabilities?

The HIR A-D chapter will attempt to ask similar questions and suggest some insight that pertains to Heterogeneous Integration for this community.

4. What is the Aerospace and Defense Sector?

Deloitte in its 2019 Global Aerospace and Defense Industry Outlook white paper10 makes the following observations:

- The commercial aircraft order backlog is at its peak of more than 14,000, with about 38,000 aircraft expected to be produced globally over the next 20 years.
- Resurgence of global military spending as geopolitical risks increase worldwide.
- Space is becoming an important part of the defense ecosystem as warfare moves into the domain of space assets such as satellites for military operations including surveillance, communications and targeting.
- Changes in international trade agreements are likely to disrupt the global supply chain and increase costs.

---

Although the USA dominates in A-D spending and revenue generation, other key regions are expected to contribute to the sector including China, France, India, Japan, the Middle East and the United Kingdom. The Aerospace and Defense sector has been at the forefront of digital innovations, leading the way for other industries in the adoption of technologies.\textsuperscript{11} The hierarchy can be shown as:

- End Customers (e.g., USG).
- System Primes (OEMs) who provide end-to-end system solutions to the end-users.
- Subsystem Suppliers who provide vital subsystems including propulsion, command and control, electronic warfare, and structural subsystems to the Primes.
- Component Suppliers that provide component parts including energetic and structural materials, microelectronics, cables, and connectors for prime and major subsystem providers.
- Pure Play Suppliers (materials, equipment, design, manufacturing, services) to other supply chain players.

Figure 4-1 highlights the differences between the Commercial and Aerospace-Defense business models. Commercial products have very short lifecycles, whereas A-D products must be supported for decades. The cost of engineering for commercial products can be amortized over millions or billions of units whereas A-D products may be in the thousands, hundreds or lower. A-D Systems are generally insensitive to unit costs but they must operate in extreme environments and have demonstrated pedigree that is tracked over the product lifecycle.

Figure 4-1. Differences between the commercial and aerospace-defense business models.\textsuperscript{12}

5. Impact of Heterogeneous Integration on Aerospace and Defense Systems

Several characteristics of the A-D sector create unique challenges:

- High Performance – Need access to leading silicon nodes and advanced packaging technologies to maintain advantage in specific technical metrics (e.g., digitization over wide bandwidths and at high dynamic range)
- High Reliability – Need to survive in harsh environments, prioritize human safety in high-risk environments
- Long Product Lifecycles – Need to manage parts obsolescence and upgradability
- Low Volumes – Need access to a supply chain that provides high product mix, and business models where NRE is managed without high volumes for amortization
- Security – Need secure domestic supply chain and/or verification technologies

Heterogeneous integration is a factor in all of these challenges, whether by adding new twists to the challenges with multiple device technologies or by solving some of them with modular designs and assemblies. Most specifically, heterogeneous integration directly addresses the high-performance challenge for the A-D sector. Monolithic System on a Chip solutions are becoming increasingly limited for A-D applications. Sustaining Moore’s Law by increasing the core count on a die is not feasible as memory access bottlenecks prevail and die size and complexity become prohibitively expensive. Diversity in process nodes and materials are needed (CPUs, GPUs, FPGAs) for enhancing performance, energy efficiency and programmability. Similarly, RF/mm-wave devices and data converters are needed for communications and sensing. Heterogeneous integration offers a way to address these limitations and sustain Moore’s Law through interconnect length reductions and optimal combinations of different device technologies. The A-D sector must adapt and adopt innovation and market drivers from the commercial semiconductor industry.

What are the metrics to consider?

There are numerous metrics to consider for heterogeneous integration in the A-D sector, and they can vary by application (communications, radar, EW, etc.). Categorized metrics include:

- **Performance**: data rate, latency, TFLOPs, insertion loss, isolation, dynamic range
- **Energy/Power**: energy per bit, TFLOPS/Joule, leakage power
- **Interfaces**: signaling protocols, error correction, interconnect lengths, ESD
- **Thermal**: maximum junction temperature, total device power, device power density, hot-spot power density, thermal test standards
- **Electrical**: power distribution losses to components inside package, losses in conversion, peak inductive noise, harmonic noise
- **Reliability/Availability**: MTBF, radiation hardness, metric related to graceful degradation upon component failures, product lifetime (driving component availability)

6. What is Heterogeneous Integration

(Refer to other HIR Chapters for the definitions of 2D, 2.1D, 2.5D and 3D heterogeneous integration)

Figure 6-1 provides a definition of heterogeneous integration, noting that heterogeneity arises from the material, component type, circuit type, node, bonding/interconnect method, or source of the devices.

The A-D component and sub-systems can benefit from the well-stated benefits of heterogeneous Integration at all levels. In this chapter, the focus is on 2.5D integration, since many 2D and 2.1D integrations and solutions are already in wide use. Chip-and-wire assembly is a standard process. Wafer-level and fan-out packages, although attractive for high-volume applications and miniaturization, may not be sufficient for high performance and harsh environments. 2.5D technology, which is represented by High Bandwidth Memory (HBM) and other applications with stacked devices on organic substrates or silicon interposers, is attractive for A-D since this approach enables higher performance and high-density integration while leveraging conventional technology building blocks.

In many ways, the A-D users have similar needs as the HPC use case. Therefore, it is recommended that A-D users leverage capabilities and supply chain partners from the HPC ecosystem (Figure 6-2).
7. 2.5D Heterogeneous Integration Progress

Heterogeneous integration via 2.5D technology is approaching mainstream status, with industry leaders such as Xilinx, Intel, Nvidia, and AMD using it in their leading products. They have identified the benefits of splitting up silicon functionality, whether to improve yield with smaller chips, as Xilinx did with their pioneering FPGA “slices,” or to enable the integration of different types of devices. To summarize:

- Chiplets (smaller pieces of silicon) will enable their silicon architects to ship more powerful processors more quickly.\(^{13}\)
- Modularity facilitates shorter time-to-market to mix and match different chiplets linked by shorter data interconnections, instead of implementing new complex SOC designs for the entire system.
- 2.5D can reduce design costs and risk by having a larger portion of the design composed of reused IP blocks that are assembled on an interposer rather than integrated in a new IC design.

Notable industry leaders see this trend. AMD’s Mark Papermaster said “I think the whole industry is going to be moving in this direction.” Similarly, Intel’s technologists see that same thing. Ramune Nagisetty, a senior principal engineer at Intel, calls it “an evolution of Moore’s law.”

Figure 7-1. DARPA’s history of integration innovation

DARPA has led the way in advancing Heterogeneous Integration Technology through a number of programs, as shown in Figure 7-1 and Figure 7-2. The DARPA DAHI program demonstrated the feasibility of 2.5D HI for

\(^{13}\) Found at https://www.wired.com/story/keep-pace-moores-law-chipmakers-turn-chiplets/
integration of CMOS devices with high-performance III-V devices through both die-to-wafer and wafer-to-wafer bonding techniques. The DARPA CHIPS program (which is still on-going) is developing a 2.5D chiplet ecosystem and a set of standard interfaces for chiplet-to-chiplet communications.

Figure 7-2. DARPA heterogeneous integration.14

7.1 DARPA DAHI Program
Daniel Green reported on the Progress and Prospects of Heterogeneous Integration at DARPA and summarized the progress made on a number of programs.15

The Diverse Accessible Heterogeneous Integration (DAHI)16 Foundry Technology program was designed to establish an accessible, manufacturable technology for device-level heterogeneous integration of a wide array of materials and devices (including, for example, multiple electronics and MEMS technologies) with complex silicon-enabled (e.g., CMOS) architectures on a common silicon substrate. This program culminated in accessible foundry processes of DAHI technology and demonstrations of advanced microsystems with innovative architectures and designs that leverage heterogeneous integration. By enabling the ability to ‘mix and match’ a wide variety of devices and materials on a common silicon substrate, circuit designers can select the best device for each function within their designs. This integration can provide DoD systems with the benefits of a variety of devices and materials integrated in close proximity on a single chip, minimizing the performance limitations caused by physical separation among devices.

Some of the key results are summarized in Figures 7-3, 7-4, 7-5, 7-6 and 7-7 below. The program demonstrated capabilities that would not have been possible in monolithic implementations, while uncovering several challenges in design, fabrication, and assembly along the way. The DAHI program has served as the baseline for heterogeneous integration at DARPA and beyond in the DoD.

7.2 DARPA CHIPS Program

The DARPA CHIPS program goals are to:¹⁷

- Establish and demonstrate common interface standards
- Enable the assembly of systems from modular IP blocks built with these established standards
- Demonstrate reusability of the modular IP blocks via rapid design iteration

Chiplets are functional, verified, modular re-useable physical IP blocks. They can be processors, converters, memory, waveform generators, accelerators, filters, etc.

A major achievement in the first 12 months of the program was the adoption of Intel’s Advanced Interface Bus (AIB) as the low-power die-to-die electrical interface. AIB offers a 1-Gbps per lane SDR transfer rate for control signals and a 2-Gbps DDR transfer rate for data. A demonstration module with an Intel FPGA and several other chips was developed and manufactured in the CHIPS program.

Figure 7-9. DARPA CHIPS program objectives to foster a chiplet ecosystem.

**Notes:**

1. Public IP is defined as IP blocks available through commercial vendors or shared among performers.
2. Reuse is defined as existing or previously designed IP that is re-implemented into the current system. Prefabricated IP is defined as IP blocks already physically instantiated.
3. Valid sources of IP must be those that are outside of the performer team.
4. Various Silicon process nodes, I/F passives, or compound semiconductor devices.
5. The non-recurring engineering (NRE) cost and turnaround time will be compared against a benchmark design.
6. Minimum bus lane data rate and should be capable of scaling to higher data rates.
7. Performance relating to transferring data between chiplets compared against a benchmark design.

7.3 DARPA PIPES Program

DARPA’s program Photonics in the Package for Extreme Scalability (PIPS) is a program that builds on CHIPS by incorporating photonic devices in a heterogeneous integration ecosystem. The vision is summarized below, and recent progress included a demonstration by Intel and Ayar Labs. (https://www.darpa.mil/news-events/2020-03-25)

---

Figure 7-17: DARPA’s PIPES program addresses HI by incorporating photonics.

8. 3D Heterogeneous Integration

True 3D Heterogeneous Integration (Figure 8-1), once developed, will provide monolithic levels in device-to-device spacing with interconnect distances in the 2 to 5um range. Significant technology challenges still exist and must be overcome to achieve the desired results. Section 8.1 describes the DARPA 3DSoC program which pushes the integration envelope to demonstrate ultra-low latency and ultra-low power I/O operations that will be needed for many AI/ML applications. Section 8.2 describes the DARPA ELGAR program which is developing dense low-loss interconnects for a G-band electronics demonstration.

Figure 8-1. 3D integration technology is an active area of research.

8.1 DARPA 3DSoC Program

A pervasive challenge for leading-edge electronic systems is the time and power required for communication between processors and memory. This “memory bottleneck” it often the primary limit on system performance.
Heterogeneous integration begins to address this by enabling closer integration of processor and memory devices, and DARPA recently initiated the Three Dimensional Monolithic System-on-a-Chip (3DSoC) program to further develop the technology required to build logic, memory, and input/output (I/O) on a single die. This approach will leverage established lithography nodes but improve performance via 3D integration. Figure 8-2 illustrates this approach, where progress is made via 3D integration rather than further advances following Moore’s Law. Figure 8-3 shows more detail of the envisioned 3D integration of novel device types.

Figure 8.2 The DARPA 3DSoC program attacks the end of Moore’s Law by the reduction of interconnect distances through vertical integration.

Figure 8-3. DARPA 3DSoC will demonstrate the tight integration of CNFET logic with ReRAM to have performance similar to FinFETs while using a 90nm fabrication line.
8.2 DARPA ELGAR Program

In 2021, DARPA MTO announced the ELeCtronics for G-band ARrays program which has two objectives: 1) Achieving efficient, compact G-band MMICs with high output power density, and 2) Achieving low loss off-chip interconnects between adjacent G-band array components. The ELGAR objectives are summarized in Figure 8-4.

The interconnect challenges are to develop:

- Approaches to heterogeneously integrate III-V MMICs with non-III-V materials such as antennas and Si ICs
- Approaches to minimize the size and loss of lateral and vertical DC and RF component-to-component interconnects while maintaining signal integrity
- High-aspect-ratio III-V through-substrate vias (TSVs)
- Optimization of RF interconnect and TSV impedance (e.g., TSV diameter/pitch) and impedance match to transmission lines to minimize loss
- Approaches that support chip-to-chip integration with micro-bumps.
- Approaches that support vertical 3D chip stacking

At 6G frequencies such as G-band (220 GHz), 2.5D integration is no longer sufficient to provide interconnect density. Therefore, novel solutions for 3D integration will need to be found. Prof. Rodwell (UCSB) summarizes the challenges for THz Phased Arrays when the lambda/2 spacing is now much less than 1 mm! It will be interesting to follow the technology development sponsored in ELGAR in the next several years (FY22 to FY26).

---

9. Outlook for the Next 5 to 10 Years

Out of the DARPA-sponsored research programs such as DARPA CHIPS, it was time to go from technology demonstration to technology capability-building. DARPA programs typically operate at Technology Readiness levels of 3 to 4 as defined by NASA. The lowest TRL suitable for insertion into a mission-critical program is TRL 6, as defined in Figure 9.1. Therefore, the US government has embarked on technology capability maturation programs which are described in Section 9.1 and Section 9.2.

![Figure 9-1. NASA Technology Readiness Levels](https://www.nasa.gov/directorates/heo/scan/engineering/technology/technology_readiness_level)

### 9.1 DoD Microelectronic Maturation Programs: RAMP and RAMP-C

In 2021, the most significant development for the Aerospace and Defense Sector is the rollout of two major DoD programs: Rapid Assured Microelectronics Prototype (RAMP) and the State-of-the-art Heterogenous Integrated

---

Packaging (SHIP) programs to develop onshore access to foundry technologies capable of meeting DoD long-term leading-edge (digital CMOS node ≤ 7nm) and advanced packaging. RAMP addresses the critical process of physical design (also called back-end design) that transforms high-level programming from register-transfer level (RTL) of a design into the complex, technology-specific layout form of a design that is required for the wafer fabrication process. In August 2021, the DoD elected Intel to provide commercial foundry services in the first phase of its multi-phase Rapid Assured Microelectronics Prototypes – Commercial (RAMP-C) program. In RAMP-C, Intel foundry services, partnered with IBM, Cadence, Synopsys and others, will support the USG’s needs for the design and manufacture of assured integrated circuits by establishing and demonstrating a semiconductor IP ecosystem based on the Intel 18A process.\(^\text{23}\) Intel also recently announced the investment of $20B to build two new factories in Arizona.

Figure 9-2 shows a diagram and relationship of RAMP and SHIP programs that support the DoD Microelectronics Roadmap.\(^\text{24}\) RAMP addresses the physical design phase and SHIP addresses the packaging and test phase. What was missing to complete the IC ecosystem is the fabrication phase. RAMP-C completes the microelectronics development lifecycle to provide DoD/DIB programs access to advanced-node CMOS device technologies through the development of a prototype Process Design Kit (PDK), foundational IP and support of critical third-party IP. The broader impacts are to strengthen supply chain security and accelerate US leadership in microelectronics.

---

Phase 2 and Qorvo was selected for SHIP-RF Phase 2, for a total award of $172.7M. The Intel SHIP effort provides the U.S. government access to Intel’s advanced heterogeneous packaging technologies, including embedded multi-die interconnect bridge (EMIB), 3D Foveros, and Co-EMIB (combining both EMIB and Foveros). The Qorvo SHIP effort provides access to Qorvo’s advanced technologies for RF to millimeter-wave state-of-the-art RF packaging capabilities.

9.3 New Legislation for Government Funding for Semiconductor Manufacturing (5 Years)

It is notable that semiconductor manufacturing is getting a lot of visibility with the proposed “CHIPS for America Act.” These incentives and investments are substantial – on the order of $52B – and the focus is on manufacturing. There is also $2.5B for Advanced Packaging, in the form of a National Manufacturing Institute. This is where the

---

Heterogeneous Integration Roadmap could help frame what is needed there, and we expect to explore this collaboration in 2021 and beyond. An additional point is the broad reach of the investments – DARPA, NSF, DoE, Dept of Commerce. That is an indicator that these manufacturing needs are not just for defense purposes. National security in electronics reaches beyond those traditional defense-specific requirements.

The CHIPS Act R&D programs, as shown in Figure 9-5, addresses the gaps in the US semiconductor ecosystem to provide the infrastructure to transition from R&D (TRL 1-4), to Prototyping (TRL 5-6) and Production (TRL 7+).

![Figure 9-5. CHIPS Act R&D Programs.](https://wwwSemiconductors.org/wp-content/uploads/2021/04/What-They-Are-Saying-Fund-the-CHIPS-for-America-Act_FINAL.pdf)

The Semiconductor Industry Association (SIA) has been in the forefront in gathering support from the USG to reverse the many decades-long decline in US leadership in semiconductors. John Neuffer, SIA President and CEO, states:

“America’s economy, national security, tech leadership, and response to COVID-19 are built on semiconductors. To remain competitive on the global economic stage and ensure more of the chips our country needs are researched, designed, and produced on U.S. shores, Congress and the White House must act swiftly to fund the semiconductor provisions in the CHIPS for America Act.”

On June 8, 2021, the Senate passed legislation called the U.S. Innovation and Competition Act (USICA) (S.1260) by a strong bipartisan vote of 68-32. USICA includes $52 billion to fund the semiconductor manufacturing, design, and research provisions in the CHIPS for America Act. Not only would the USICA benefit the Department of Defense for national security, but it is considered vital to the economic vitality of many of our commercial industries including automotive, consumer, transportation, and IT sectors. SIA has issued a report that provides quotes from key industry leaders. The USICA is in the process of being funded by Congress.

Potential beneficiaries of the USICA funding include Intel, GlobalFoundries and Samsung. On July 19th 2021, GlobalFoundries said that it will build a second factory near its Malta, New York, headquarters, and spend $1 billion.

---

to boost output to address the global chip shortage. On November 24, 2021, Samsung Electronics Announces New Advanced Semiconductor Fab Site in Taylor, Texas with $17B in investments.

A second key piece of legislation, “The Facilitating American-Built Semiconductors (FABS) Act,” has been proposed in 2021. This legislation proposes a 25 percent investment tax credit for investments in semiconductor manufacturing, both for manufacturing equipment and for the construction of semiconductor manufacturing facilities. The proposal includes incentives for the manufacture of semiconductors, as well as for the manufacturing of the specialized tooling equipment required in the semiconductor manufacturing process. As of Oct. 28, 2021, the reconciliation package included a modified version of the Facilitating American-Built Semiconductors (FABS) Act, legislation to provide an investment tax credit to incentivize semiconductor manufacturing in the United States.

A comprehensive State of the Industry Report was issued by SIA on September 27, 2021. Key findings include:
- Despite the uncertainty in demand caused by the COVID-19 pandemic, the global market grew substantially in 2020, and the outlook is strong for the remainder of 2021 and beyond.
- For some business model subsegments, the U.S. industry lags its Asian-based competitors.
- Industry R&D expenditures are consistently high, reflecting the inherent link between U.S. market share leadership and continued innovation.
- The U.S. semiconductor industry maintains one of the highest levels of R&D as a percentage of sales of any U.S. industry.
- U.S. semiconductor manufacturing capacity has significantly decreased as a share of global capacity.

9.4 Modular Single-Wafer Fabrication (5 to 10 Years)

Recent research in Japan is developing a concept called “minimal fab” which is an early example of the type of solution that could enable high-mix, low-volume production of semiconductors with approaches more typical of high-volume manufacturing. Small lots manufactured in this low-overhead approach could be an enabler for heterogeneous integration, especially for low to medium volumes as in A-D.

Figure 9-6. Minimal modular wafer fabrication technology.

TOKYO Semiconductor start-up NEITAS has succeeded in creating semiconductor components in 20 hours – just a fraction of the time normally required – using a “minimal fab,” a system that can produce even a single wafer with low capital spending. The breakthrough was confirmed jointly with Toyohashi University of Technology in

Toyohashi, Aichi Prefecture. The company plans to set up a contract fabrication plant in Okinawa by the end of the year with the aim of achieving 10 billion yen ($88.4 million) in sales by 2020.\(^{35}\)

The minimal fab was born at the National Institute of Advanced Industrial Science and Technology (AIST) in Tsukuba, Ibaraki Prefecture. It can manufacture semiconductors using small wafers just 12.5mm, or 0.5 inch, in diameter. Masks are not required because of novel lithography. Using a maskless technology developed at Toyohashi University, the equipment is capable of defining 0.8 micron dimensions. Although this is quite coarse for CMOS FEOL, this is in the right ballpark for BEOL linewidths, so the most advanced lithography tools are not needed. Clean rooms are also unnecessary because the processing is performed in enclosed spaces within the equipment.

At "SEMICON Japan 2017"\(^{36}\), Minimal Fab exhibited their equipment that houses self-contained processing capability for wafer cleaning, and exposure for wafers as small as 0.5 inch. A minimal shuttle container is used to move the wafer between processing machines. This type of equipment is suitable for small-lot production and is useful for research and development with drastically reduced capital costs. Minimal Fab is working with Disco, Ishii Craft Research Institute, Apic Yamada and others to foster a minimal-equipment ecosystem. Yokogawa Solution Service\(^{37}\) will act as a contact point to order and sell various equipment from different manufacturers.\(^{38}\)

In 2019, the Minimal Fab approach was used to fabricate ICs for use in space electronics (Figure 9-8), in a joint effort with Japan Aerospace Exploration Agency (JAXA) and Japan’s National Institute of Advanced Industrial Science and Technology (AIST). While this is still in development, it is an interesting proof point for a new approach to semiconductor manufacturing that could prompt additional work on concepts that could help address the specific challenges of A&D electronics.

10. **DARPA Electronics Resurgence Initiative (ERI)**

In 2018, DARPA’s Microsystem Technology Office (MTO) launched the Electronics Resurgence Initiative (ERI).³⁹

- Today’s critical Department of Defense (DOD) systems and platforms rely on advanced electronics to address national security objectives.
- To help tackle obstacles facing a half-century of electronics advancement, DARPA launched the Electronics Resurgence Initiative (ERI) – a five-year, upwards of US$1.5 billion investment in the future of domestic electronic systems.

Figure 10-1 shows the updated vision of ERI from DARPA’s ERI Summit in August 2020. Heterogeneous integration is the cornerstone of many ERI programs, facilitating capabilities possible only with a diversity of devices.

---

11. **Supply Chain**

### 11.1 International Supply Chain

The NDIA Trusted Microelectronics Team 1 Report asks: “Increasing Supply Chain Complexity: Commercially available capability (complex global infrastructure involved in SOTA designs; Fab, IP, Packaging, Testing, etc.) is rapidly increasing, accomplished through a complex disaggregated supply chain that is fragile and subject to compromise. How can it be safely utilized?”⁴⁰

---

• Foundries concentrated in Asia
• Chinese players growing
• Increasingly consolidated among leaders

Access must also be reiterated here as a critical challenge and concern. While access to trusted components is already understood as a core concern, simple access to the parts needed from the larger global electronics industry base is an even larger concern. Figure 11-1 describes this concern, and emphasizes the need to take seriously the larger strategic issue of continued assured access to components for our current and future DoD systems.

This is a major concern as the globalization and consolidation of microelectronics companies is driven by demand in the commercial markets rather than by the needs within the Defense markets. Achieving continued assured access to advanced microelectronics components is imperative for the DoD to maintain the strongest Defense and Intelligence communities in the world. Without a coherent national strategy, the US government risks losing its ability to protect its key systems, and the US microelectronics industry will lose its leadership role in this critical market. Figures 11-2 through 11-5 provide recent data on geographic distribution of semiconductor manufacturing leaders.

Figure 11-6 shows the distribution of semiconductor industry market share by activities versus countries. Most EDA tools and IP creation is from the US and/or Europe. The US share of wafer fabrication is now down to 12% and is dominated by Asian countries. That the US share of packaging is 2% points to the need for on-shore IC packaging through USG programs like SHIP and corporate investments.

Finally, there is the White House report on “Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad-based Growth,” Executive Order E.O. 14017. It addresses:

- A COVID-19 Response Team has drastically expanded the manufacture of vaccines and other essential supplies, enabling more than 137 million Americans to get fully vaccinated.
- Working with companies that manufacture and use semiconductor chips to identify improvements in supply chain management practices that can strengthen the semiconductor supply chain over time.
- The Department of Defense (DOD) has announced an investment in the expansion of the largest rare earth element mining and processing company outside of China to provide the raw materials necessary to help combat the climate crisis.
- Working to address critical cyber vulnerabilities to U.S. supply chains and critical infrastructure, including issuing E.O. 14028 on “Improving the Nation’s Cyber Security.”

12. Aerospace and Defense Roadmap, Rev. 0.4

Figure 12-1 is the first high-level roadmap table for HIR A&D. This is more qualitative than quantitative at this point, but we expect that to evolve somewhat as we drill down with more specifics. There will also be links to other HIR chapters with more details on certain topics, such as photonics, thermal management, and 3D interconnect. The A&D TWG will work on gathering inputs for the version that will appear in the 2022 update.
